Provides coverage of Motor Current Signature Analysis (MCSA) for cage induction motors This book is primarily for industrial engineers. It has 13 chapters and contains a unique data base of 50 industrial case histories on the application of MCSA to diagnose broken rotor bars or unacceptable levels of airgap eccentricity in cage induction motors with ratings from 127 kW (170 H.P.) up to 10,160 kW (13,620 H.P.). There are also unsuccessful case histories, which is another unique feature of the book. The case studies also illustrate the effects of mechanical load dynamics downstream of the motor on the

interpretation of current signatures. A number of cases are presented where abnormal operation of the driven load was diagnosed. Chapter 13 presents a critical appraisal of MCSA including successes, failures and lessons learned via industrial case histories. The case histories are presented in a step by step format, with predictions and outcomes supported by current spectra and photographic evidence to confirm a correct or incorrect diagnosis The case histories are presented in detail so readers fully understand the diagnosis The authors have 108 years of combined experience in the installation, maintenance, repair, design, manufacture, operation and condition monitoring of SCIMs There are 10 questions at the end of chapters 1 to 12 and answers can be obtained via the publisher Current Signature Analysis for Condition Monitoring of Cage Induction Motors serves as a reference for professional engineers, head electricians and technicians working with induction motors. This book is about electric energy: its generation, its transmission from the point of generation to where it is required, and

its transformation into required forms. To achieve this end, a number of devices are essential—such as generators, transmission lines, transformers, and electric motors. We discuss the design, construction, and operating characteristics of the electric devices used in the transformation to and from electric energy. This text is designed to be used in a one-semester course in electric energy conversion at the second-year level of the Bachelor of Engineering course. It is assumed that the student is familiar with the laws of thermodynamics and has taken a course in basic circuit analysis, including the application of phasors. We begin with a discussion of how humankind has successfully harnessed the energy of wind, water, the sun, biomass, animals, geothermal sources, fossils, and nuclear fission to make its life comfortable. Some of the consequences of this activity on the environment are examined. In Chapter 2, we review the basic physics of energy and its conversion. This may be, to some extent, a repetition of knowledge gained in high-school and first year university courses. However, we believe that such review is necessary to establish a suitable base from which to launch the subject of electric energy conversion.

The main models discussed are based on the: i) Maxwell-Fourier method (i.e., the formal resolution of Maxwell's equations by using the separation of variables method and the Fourier's series in 2-D or 3-D with a quasi-Cartesian or polar coordinate system); ii) electrical, thermal and magnetic equivalent circuit; iii) hybrid model. In these different papers, the numerical method and the experimental tests have been used as comparisons or validations.

An Introduction to the Engineering Principles and Characteristics, Theory, Design, and Performance Calculations of Split-phase, Capacitor, and Polyphase Induction Motors in the Fractional-horsepower and Small Integral-horsepower Ranges John Wiley & Sons

Automotive companies are actively seeking major improvements in electric motors, power electronics, and energy storage systems. The industry is pursuing advances in the torque output, power density, and overall efficiency of electric motors used in vehicles. This dissertation investigates a three-phase stator winding configuration that would produce a one-sided magnetic field. The design was created in hopes of increasing the torque output and power density of the motor, without effecting the overall efficiency of

the motor. Both an 8-pole PMSM and a 4-pole induction motor stator winding design are studied. A Toyota Prius IPM motor and Baldor EM3218T motor are used for the baseline motor in each design case. A Halbach array arrangement of three-phase coils is implemented. A three-phase Halbach array is created to validate the initial design concept. The stator winding design is improved by studying the strength of the magnetic flux density in the stator and correcting areas of saturation. The reluctance path of the magnetic flux through the stator is also heavily examined in this research. The shape and arrangement of individual coils in the stator are optimized for maximum torque output of the motor. Comparisons of performance characteristics are made between the new stator winding design and the baseline motors. Major challenges hindering the performance of the three-phase stator winding configuration are explained. Lastly, suggestions and possible areas of future research associated with the stator winding configuration are discussed.
