one-of-a-kind introduction to the theory and application of modeling and simulation techniques in the realm of international studies Modeling and Simulation for Analyzing Global Events provides an orientation to the theory and application of modeling and simulation techniques in social science disciplines. This book guides readers in developing quantitative and numeric representations of real-world events based on qualitative analysis. With an emphasis on gathering and mapping empirical data, the authors detail the steps needed for accurately analyzing

global events and outline the selection and construction of the best model for understanding the event's data. Providing a theoretical foundation while also illustrating modern examples, the book contains three parts: Advancing Global Studies—introduces the what, when, and why of modeling and simulation and also explores its brief history, various uses, and some of the advantages and disadvantages of modeling and simulation in problem solving. In addition, the differences in qualitative and quantitative research methods, mapping data, and conducting model validation are also discussed. Modeling Paradigms—examines various methods of modeling including system dynamics, agent-based modeling, social network modeling, and game theory. This section also explores the theory and construction of these modeling paradigms, the fundamentals for their application, and various contexts for their use. Modeling

Global Events—applies the modeling paradigms to four real-world events that are representative of several fundamental areas of social science studies: internal commotion within an anarchic state, a multi-layered study of the Solidarity movement in Poland, uni-lateral military intervention, and the issue of compellence and deterrence during a national security crisis. Modeling and Simulation for Analyzing Global Events is an excellent book for statistics, engineering, computer science, economics, and social sciences courses on modeling and simulation at the upper-undergraduate and graduate levels. It is also an insightful reference for professionals who would like to develop modeling and simulation skills for analyzing and communicating human behavior observed in real-world events and complex global case studies.

Modeling, simulation, and analysis (MS&A) is a crucial tool for military affairs. MS&A is one of the announced pillars of a strategy for transforming the U.S. military. Yet changes in the enterprise of MS&A have not kept pace with the new demands arising from rapid changes in DOD processes and missions or with the rapid changes in the technology available to meet those demands. To help address those concerns, DOD asked the NRC to identify shortcomings in current practice of MS&A and suggest where and how they should be resolved. This report provides an assessment of the changing mission of DOD and environment in which it must operate, an identification of high-level opportunities for MS&A research to address the expanded mission, approaches for improving the interface between MS&A practitioners and decision makers, a discussion of training and continuing education of MS&A practitioners, and an examination of the need for coordinated military science research to support MS&A.

Research shows that in a system model, when the production rate is adjusted based on the number of items in queue, the nature of the model changes from an open-loop queueing system to a closed-loop feedback control system. Service-rate adjustment can be implemented in a discrete event simulation model, but the effect of this adjustment has not been thoroughly analyzed in the literature. This research considers the design of

feedback signals to generate realistic simulation models of production system behavior. A series of simulation experiments is conducted to provide practical guidance for simulation modelers on how adding a service-rate adjustment feedback loop to a queueing system affects system performance.

Use and Analysis John Wiley & Sons

In this study, the potential use of a simulation model as a decision support tool for ship production has been developed and evaluated. Discrete event manufacturing simulation proved to be an effective method for analyzing the system and answering the key manufacturing questions. The illustrative case study has shown that following a detailed network model of ship production operations, the application of simulation provides valuable data for plant utilization as well as important decision support information for the required management actions. Planning and control of the shipbuilding process is a series of complicated activities due to make-to-order and mostly non-repetitive nature

of operations performed. This situation is introduced to the system by three main sources; complexity of operations, stochastic and dynamic nature of processes, and uncertainties imposed to the system by the shipyard's outer environment as well as its own resources. The simulation approach as presented in this study allowed the modeling and analysis of the ship production as a stochastic system, which has proved to be too complex to be effectively modeled by other analytical tools. The related research survey showed that the previous conventional/classical deterministic Network Analysis Techniques such as the Critical Path Method (CPM) and the Project Evaluation and Review Technique (PERT) assume that the activity and project durations are deterministic (or completely fixed). In order to account for prevailing uncertainties, stochastic network analysis techniques have been developed. While above-mentioned techniques may provide some useful information about certain aspects of the performance of the system, the simulation approach proves to be the most capable method of answering the key manufacturing questions. The main outcome of this research is the conclusion that the simulation modeling and analysis of the ship production system proved to be a feasible means of decision aid to the decision maker. The results of this study leads to a following conclusions concerning the potential use of simulation modeling and analysis in the ship production environment; 1) Detailed network model is a valuable tool for every ship production operation, 2) Collection of the production data is considered to be the most critical effort during the modeling stage of the system, 3) The stochasticity is introduced to the study by modeling the system randomness, 4) The

evaluation of different operating scenarios or experiments and design alternatives by building an imaginary description of sequences of events is a major benefit of simulation studies and helps to examine the details of dynamics of alternative events, rather than only the isolated individual domain of modification, 5) Simulation modeling and analysis provide invaluable information for management actions.

Modeling and Simulation Based Analysis in Reliability Engineering CRC Press

Models and simulations of all kinds are tools for dealing with reality. Humans have always used mental models to better understand the world around them: to make plans, to consider different possibilities, to share ideas with others, to test changes, and to determine whether or not the development of an idea is feasible. The book Modeling and Simulation uses exactly the same approach except that the traditional mental model is translated into a computer model, and the simulations of alternative outcomes under varying conditions are programmed on the computer. The advantage of this method is that the computer can track the multitude of implications and consequences in complex relationships much more quickly and reliably than the human mind. This unique interdisciplinary text not only provides a self contained and complete guide to the methods and mathematical background of modeling and simulation software (SIMPAS) and a collection of 50 systems models on an accompanying diskette. Students from fields as diverse as ecology and economics will find this clear interactive package an instructive and engaging guide.
